

coupled individual wavelengths pass through the binary tree to the plurality of K multiplexers while every undesired path of the individual wavelengths through the binary tree encounters both a closed 1x2 switch and shutter so as to block undesired crosstalk signals into said multiplexers.

2. (Original) The invention defined in claim 1 wherein the outputs of each switch are waveguides crossing each other to form inputs to the switches in the next stage.
3. (Original) The apparatus of claim 1 wherein said demultiplexer, said binary tree, and said multiplexers are all formed in a planar arrangement on one or more substrates.
4. (Original) The apparatus of claim 3 wherein the demultiplexer and said multiplexers are waveguide grating routers.
5. (Original) The apparatus of claim 3 wherein said switches are Mach-Zehnder interferometers.
6. (Original) The apparatus of claim 5 wherein said switches are activated thermooptically.
7. (Original) The apparatus of claim 1 in which the outputs of said multiplexers are connected to an  $N \times N$  waveguide grating router.
8. (Canceled).
9. (Currently Amended) An integrated wavelength router comprising  
a binary tree comprising at least first and second stages of interconnected  $1 \times 2$  switches,  
a demultiplexer arranged to couple  $N$  individual wavelengths in a WDM optical signal to  
inputs of respective switches in said first stage,  
a plurality of  $K$  multiplexers arranged to combine outputs from a plurality of switches in said  
second stage to form outputs of said router, and

further comprising a plurality of shutters disposed before the inputs of said multiplexers and operated in conjunction with the binary tree so as to dilate said router so that desired paths of coupled individual wavelengths pass through the binary tree to the plurality of K multiplexers while every undesired path of the individual wavelengths through the binary tree encounters both a closed 1x2 switch and shutter so as to block undesired crosstalk signals into said multiplexers.

10. (Currently Amended) A router comprising

  a binary tree containing  $\log_2 K$  stages of interconnected  $1 \times 2$  switches,

  a demultiplexer arranged to receive an input WDM signal containing  $N$  wavelengths, and apply  $N$  separated wavelengths to inputs of switches in a first of said  $\log_2 K$  switch stages,

$K$  multiplexers arranged to combine outputs from switches in the last of said  $\log_2 K$  switch stages to form  $K$  outputs of said router, and

  further comprising a plurality of shutters disposed before the inputs of said multiplexers and operated in conjunction with the binary tree so as to dilate said router so that desired paths of coupled individual wavelengths pass through the binary tree to the plurality of K multiplexers while every undesired path of the individual wavelengths through the binary tree encounters both a closed 1x2 switch and shutter so as to block undesired crosstalk signals into said multiplexers.

11. (Original) The router of claim 10 wherein said switches are integrated in a planar arrangement on one or more silica substrates, and wherein the outputs of the switches in each of said stages cross each other before being connected to inputs of the switches in the next stage.

12. (Canceled).

13. (Original) The invention defined in claim 10 wherein the outputs of each switch are waveguides crossing each other to form inputs to the switches in the next stage.
